Adversarial review of the page

eleicoes.radzkitech.com, state of 29 Oct 2026 (local build, branch with the biometrics changes). Four independent reviewers, one per part of the page, checked each claim against the data and scripts behind it. Items marked **verified** were re-checked against the data before this report; **not re-run** means the finding comes from one reviewer only.

> The numbers on the page are right: all four reviewers reproduced the figures in their sections from the data. The problems are in interpretation: in several places the page labels as normal, or explains away, things the data doesn't support.

Most serious: anomalies presented as normal

1. **Vote concentration is labelled “Normal”, but 2026 is far outside both reference years.** Among sections where the PT got 90% or more, those that also had 90%+ turnout were 11.0% in 2026, against 4.5% in 2022 and 5.2% in 2018. **Verified.**
2. **The “1.4% of the margin” bound is too narrow.** It counts only sections where Lula got 90%+. The turnout rise is a smooth gradient with how pro-Lula a section was: +0.9 points in balanced sections, +2.8 at 70–80%, +3.8 at 80–90%, +4.1 at 90%+ (**verified**). The reviewer estimates about 845k extra voters across all sections with 70%+ for Lula, about 19% of the margin. Question 9's own Shpilkin bound (Lula still wins by 3.12 M) already says more. Neither bound comes close to flipping the result.
3. **High-turnout sections lean to Lula well beyond chance (about 5.7σ), and the page doesn't say so.** The comparison uses 50% as “chance”, but the real baseline is 47.5%. The reviewer found the benign explanation in the data: the same sections already leaned Lula in round 1, and two-thirds were already turnout outliers then. **Not re-run.**

Baselines that flatter the result

4. **“Pure chance would give about 143 on each side” is wrong.** That 143 uses a normal curve with the data's own spread (1.18); pure chance gives about 15. The comparison with 2022, the real argument, still holds. **Verified in the code.**
5. **“2026 passes every test” contradicts the table's own |z| > 2 rule.** Blank and spoiled votes have z of −3.0 and −4.7, though in the direction opposite to fabrication.
6. **The chi-squared test's “1 would be just chance” is wrong.** With small polling places, chance alone gives a median of about 0.84.

Planted-fraud checks that couldn't happen in reality

7. **The bursts test plants 20 extra votes per near-unanimous machine.** None of the 92 has 20 absentees (median 6), so its “7.5% → 16.3%” is impossible. **Verified.**
8. **The Klimek model sentence is contradicted by the model itself.** The page says the 92 near-unanimous sections “fit the clean distribution”. The model's “extreme fraud” sits at about 99% turnout and 99% share, while the real 92 have a median

turnout of 96%. The model's own clean fit produces almost none of them, so it simply can't see this shape. **Model parameter and median verified.**

9. **The intro says every planted fraud is sized to flip the result.** That's true for only three tests; the Klimek, bursts, expected×observed and detector plants are much smaller.
10. **The simulator says “Sim, it shows” whenever a number moves 4σ from the true 2026 value**, which no analyst ever has. Several frauds marked “Sim” leave numbers within normal 2022-to-2026 variation. Related problems:
    - “Inventing numbers” has rounding built in, which is what the last-digit test catches.
    - Independent random draws in each round create the swing flags.
    - Unticking “both rounds” promises a mark that doesn't appear.
    - “Stuffing” overstates the number of complicit sections by 30%.

Factual or descriptive errors

11. **“His share rises over the count, in 2022 as in 2026” is wrong for 2026.** Lula opened at 55.5%, fell to 49.5% at about 22% counted, and passed 50% again only around half counted. **Verified.** The cause the page gives (arrival order by region) does reproduce the dip.
12. **The method notes name the printed tally report as the check against a uniform shift.** That report comes from the same software, which the simulator's own text points out.
13. **Smaller issues:**
    - The machine-model comparison is diluted: only 14% of sections share a polling place with another model.
    - The expected×observed model uses runoff turnout as a predictor, and its pro-PT/anti-PT ratio flipped from 0.6 to 1.25 without comment.
    - The swing “bound” isn't a real upper limit.
    - The “aldeia, povoado…” list omits “indígena”, which matches 20 of the 28.
    - The page says “1.000 machines drawn”; it's 999.
    - Two tables show abstention totals that differ by about 100.
    - The 2018 “near-unanimous for Lula” were Haddad's sections.
    - “The logs show the opposite” overclaims; the same-place comparison shows “the same”.

Not verifiable from the repo

Outside facts (OAS quotes and times, Zanin's ruling, polls, the Armed Forces report), the integrity-test sample sizes for 2026 (the source is unnamed news reports), and the “58 of 641” figure for 2022.

Verdict

The arithmetic is sound, and the headline conclusion still holds: no bound on these signals comes near flipping the result. But the page is partly wrong in how it presents some

evidence. Items 1–3 and 7–8 would hurt most if a critic found them first.
